***Abstract*—This study introduces a new way to automatically spot retinal diseases by analyzing Optical Coherence Tomography (OCT) images. We used four public datasets OCT-C8, OCT-2017, OCT-Duke-Srinivasan-2014, and AMD-2014 to train and test our model. These datasets include a mix of retinal conditions like AMD, CNV, CSR, DME, DR, DRUSEN, MH and healthy retina images. Before training the data into the model, we did some cleaning up, like resizing images, normalizing them, augmenting the data to add variety, and reducing noise to help the model learn better. Our proposed model is a hybrid setup that combines Convolutional Neural Networks (CNN) for pulling out important features from the images with a Vision Transformer (ViT)-based part to catch long-distance relationships. To make the model even more accurate, we developed a new Poly Loss Function to improve training. The CNN (based on ResNet) handles feature extraction, then the transformer layer works to fuse these features before the final classification. We tested our model on a separate validation set, and it beat current top models, hitting an accuracy of 97.25%, a sensitivity of 97.00%, a specificity of 97.50%, and an AUC of 0.9797. Plus, we included Explainable AI tools like Class Activation Maps (CAM) and Shapley Additive Explanations (SHAP) to make the model's decisions easier to understand—which is super important if this is going to be used in clinics. Our results show that this model can reliably classify OCT images into different retinal disease categories, which could really help in clinical settings. We did find some challenges, like dealing with subtle retinal details and noisy images, but overall, this work sets the stage for more trustworthy, transparent, and automated retinal disease diagnosis, making eye exams smoother and more accurate.**

***Index Terms*—Retinal Disease Detection, OCT, CNN, ViT, Hybrid Deep Learning Model, XAI, CAM, SHAP, Machine Learning, Transfer Learning**

I. Introduction

Our eyes are one of the most important parts of our body, and problems with vision can really affect how we live, work, and stay independent. Around the world, millions of people suffer from retinal diseases, and if left untreated, they can lead to blindness.

Some of the most common retinal issues include Diabetic Retinopathy (DR), Age-related Macular Degeneration (AMD), Glaucoma, Diabetic Macular Edema (DME), Choroidal Neovascularization (CNV), and Drusen.

These diseases can affect different parts of the retina and often cause symptoms like black spots, blurry vision, or even complete vision loss. For example, DR happens when high blood sugar damages the tiny blood vessels in the retina [1]. AMD mainly affects the central part of the retina called the macula, and it tends to happen more in older adults [2]. Glaucoma is caused by increased pressure inside the eye that harms the optic nerve. Since these conditions often develop quietly without obvious early signs, getting regular eye check-ups is key [3].

To diagnose these issues, eye doctors typically use fundus camera images or optical coherence tomography (OCT). But manually analysing these images takes a lot of skill and time, and between different doctors, the results can vary. In small clinics or rural areas where there aren't many specialists, patients might not get diagnosed early enough, which can cause permanent damage to their vision.

To tackle this, researchers have been working on automated systems that can detect eye diseases from fundus or OCT images-these are called Computer Aided Diagnostic (CAD) systems. In earlier days, most CAD systems used machine learning techniques like decision trees or clustering algorithms, which required experts to manually identify important features. However, these methods often struggled when images were poor quality or the signs weren't obvious.

Recently, deep learning has shown incredible promise in medical image analysis, especially for spotting eye conditions. Convolutional Neural Networks (CNNs), a popular type of deep learning model, can automatically learn and extract features from raw images without needing humans to do feature extraction. When it comes to diseases like DR, AMD, and DME, these models are achieving very high accuracy. To make results even better and more understandable, newer models like transformers are also being explored.

In our study, we introduce a hybrid deep learning model that combines ResNet, a CNN, with LSTM, a sequential model, to better classify retinal diseases from fundus images. We also incorporate Explainable AI (XAI) techniques such as Grad-CAM to show which parts of an image influenced the model's predictions. This helps doctors better understand and trust the model's decisions.

Our combined ResNet and LSTM model hits about 96.25% accuracy, outperforming many traditional CNN approaches.

We use Grad-CAM visuals to emphasize key regions of each image, making the system more transparent and practical for clinical use. We tested our model on a standard dataset and evaluated it with several performance metrics to ensure strong results.

Paper Organization: Section II reviews related work. Section III outlines the dataset. Section IV explains model architecture and training. Section V discusses results. Section VI concludes with future directions.

II. Related Work

Over the past decade, we have seen some pretty exciting progress in how AI is used to automatically detect and classify retinal diseases through OCT images. These days, deep learning models-especially convolutional neural networks (CNNs)-are the go-to tools for analyzing these images. They're really good at picking up on the complex features and patterns that aren't obvious at first glance.

Back in 2018, Kermany et al. [4] and colleagues used OCT images with deep transfer learning to spot diabetic retinopathy. Their results showed that these new models could do a better job than older methods, especially when it came to catching early signs of the disease—they were quite accurate too.

Then in 2020, Bhadra et al. [5] built a deep multi-layer CNN that could classify OCT images into categories like healthy, dry AMD, wet AMD, and DME, with high accuracy and solid performance. Later that year, Das et al. [6] developed a Multi-Scale Deep Feature Fusion (MDFF) network. This approach combines different types of features, which helps improve classification accuracy, especially for tricky conditions like AMD and DME, because it integrates more information.

More recently, in 2021, Wen et al. [7] introduced a Lesion-Localization Convolutional Transformer (LLCT), which mixes CNNs great at extracting local details with transformers that get the overall picture. This combo proved to be really effective for both classifying and locating lesions within OCT images, pushing the accuracy and localization far beyond previous levels. The mix of CNNs and transformers really shows how combining local and global info can take OCT image analysis to the next level.

On top of that, Saleh et al. [8] in 2022 looked into using transfer learning to classify OCT images and diagnose retinal issues. Their research emphasizes how pre-trained networks can dramatically improve diagnosis accuracy, especially in cases where resources are limited. Basically, large, pre-trained models can be fine-tuned with minimal effort to achieve pretty impressive results.

In addition, there's a growing focus on making these AI models more understandable. Explainable AI (XAI) tools are becoming key, especially in medicine, because they help doctors see why a model made a certain decision. Techniques like attention mechanisms and saliency maps emphasize the important areas in OCT images that influence diagnosis, making everything more transparent and trustworthy. These methods allow clinicians to really understand the reasoning behind a model's predictions, which boosts their confidence and trust in the technology. For example, attention mechanisms and saliency maps have been used to focus on the relevant regions in OCT images that contribute to a particular diagnosis, enhancing the interpretability of the model [8].

In our own research, we want to build on these ideas by directly integrating XAI techniques into our OCT analysis pipeline. By combining advanced deep learning models with explainability tools, we aim to not only enhance how accurately our system detects retinal diseases but also make it easier for doctors to understand and trust the results. We're experimenting with a hybrid setup that merges CNNs with transformer-based architectures, so we get better performance and clearer explanations for our predictions.

III. Data Description

Four publicly available datasets were used in the study to train and test the retinal disease detection model from OCT images. The datasets are widely used in the research community for retinal disease classification and contain a good set of samples from various sources.

A. Dataset Source: Public Dataset

The data sets used in this research were obtained on Kaggle, a data repository that contains a range of public data sets that can be used for research. The data set consists of a range of retinal diseases, such as Age-Related Macular Degeneration (AMD), Diabetic Macular Edema (DME), and other retinal pathologies.

B. Key Attributes:

OCT-C8 Dataset: The dataset consists of 24,000 OCT images that belong to eight classes. AMD (Age-Related Macular Degeneration), CNV (Choroidal Neovascularization), CSR (Central Serous Retinopathy), DME (Diabetic Macular Edema), DR (Diabetic Retinopathy), DRUSEN (Deposits in the retina), MH (Macular Hole), and Normal. The dataset includes a solid collection of images that cover both normal and abnormal retinal conditions [9].

OCT-2017 Dataset: The dataset has about 84,495 images and has four classes: CNV (Choroidal Neovascularization), DME (Diabetic Macular Edema), DRUSEN (Deposits in the retina) and Normal. This dataset's also well classified with the disease as well as train and test separation. But this dataset has fewer categories to sort than the OCT-C8 dataset [10].

OCT-Duke-Srinivasan-2014 Dataset: The dataset consists of about 4221 OCT scan images that are solely designed for training deep models for retinal pathology with particular focus on AMD, DME and Normal pathologies. It is a normally distributed one between the normal and abnormal class [11].

AMD-2014 Dataset: The dataset is made up of 269 high quality OCT images belonging to only AMD classes. The dataset was used in several past research studies to evaluate AI models for retinal disease detection and classification [12].

C. Data Preprocessing:

The datasets underwent several preprocessing operations to get the data in clean and high-quality form to be trained and tested. They consisted of: Normalizing the pixel values helps to bring all the images into the same range, from 0 to 1. Data augmentation operations like rotation, flip, and zoom to introduce diversity in the training set to avoid overfitting.

Resizing of images to map all the images to the same size to feed into the neural network.

Noise reduction techniques were used on the OCT scans to reduce artifacts, making it easier for the models to focus on the important features instead of noise.

D. Bias & Limitations:

Even though the datasets are public domain and have extremely wide usage, there are some limitations to them:

- **Imbalanced Class Distribution:** One can have an imbalanced class distribution for certain data sets with certain diseases underrepresented. This would impact on the performance of the model in the underrepresented classes.
- **Limited Scanning Condition Diversity:** The data sets are primarily composed of OCT images scanned under standard conditions. Differences in image quality or scanning methods could lead to biases to the generalization of the model.
- **Lack of Demographic Information:** Many of the databases do not have data regarding the age, sex, or ethnicity of the subjects, and these might be useful variables to disease diagnosis for the retina and might also lower the findings to broad groups.

IV. Methodology

This section outlines the methodology and approach employed in the detection of retinal diseases using an Explainable AI (XAI) model that was trained on OCT images. The proposed model is a deep learning model based on transformer architecture for the classification of retinal diseases and with transparency and interpretability for the purpose of aiding clinical diagnosis.

A. Data Collection and Preprocessing

Four publicly available OCT image datasets were used:

- OCT-C8 Dataset: 24,000 images classified as AMD, CNV, CSR, DME, DR, DRUSEN, MH and Normal.
- OCT-2018 Dataset: 84,000 images categorized into CNV, DME, DRUSEN and Normal.
- OCT-Duke-Srinivasan-2014 Dataset: Approximately 4,221 balanced images labelled as AMD, DME and Normal for retinal disease classification.
- AMD-2014 Dataset: a total of 269 images AMD images. All datasets were subjected to various preprocessing procedures to make them consistent and of high quality:
- Image Resizing: All images were resized to 256×256 pixels.
- NORMALIZATION: Pixel values were normalized to [0,1] so that inputs [9]–[12] are standardized.
- Data Augmentation: Rotation, flipping, and zooming were applied to improve generalizability and prevent over-fitting [13].
- Noise Reduction: Median filtering was used to help get rid of any unwanted visual noise or weird-looking spots in the images.

B. Model Architecture

The model combines convolutional and transformer-based components with a novel loss function:

- Transformer Network: A vision transformer (ViT)-based central unit processes features based on self-attention mechanisms to achieve long-range dependencies and contextual understanding [14].
- Multi-Scale Feature Fusion: CNN features of different scales extract local features which are concatenated before classification [15].
- Poly Loss Function: The Poly Loss Function gives strong gradient signals even in tough situations, helping the model learn better overall and spot rare diseases more accurately [16].

C. Model Training

The model was primarily trained on the OCT-C8 dataset:

- Train-Validation Split: 80% train, 20% validation.
- Feature Extractor: A ResNet based CNN was used to pick out features from the images, and then those features were sent into the transformer layer.
- Loss Function: Poly loss was employed to direct the optimization process.
- Optimizer: Adam optimizer helped in efficient convergence.
- Epochs and Early Stopping: The model was trained for 10 epochs with early stopping based on validation loss and accuracy measures [**?**]

D. Model Evaluation and Validation

The model was validated on the remaining three datasets to check for robustness and generalizability:

- Accuracy: Total classification accuracy across classes.
- Precision, Recall, F1-Score: For measuring performance at individual categories, especially to detect latent diseases.
- Confusion Matrix: For visualisation of misclassification's and prediction bias. The proposed model performed better than baseline models and achieved or even exceeded state-of-the-art performances.

E. Explainability and Interpretability:

The model contains the following XAI tools for clinical trust to be ensured:

- Class Activation Maps (CAM): Emphasizes on images showing which parts the model focused on when making a decision, helping doctors see what the model was paying attention to [**?**].

- SHAP (Shapley Additive Explanations): Quantified feature contributions to model predictions on a pixel-wise level, improving decision-making transparency [**?**].

F. Hyperparameter Tuning

Hyperparameters like learning rate, batch size, and transformer depth were tuned using both grid search and random search methods. 5-fold cross-validation was employed to avoid overfitting and ensure stability.

G. Final Contribution

This work presents a hybrid model combining CNN-based feature extraction, transformer attention, and XAI explainability methods. Using multi-scale learning and Poly loss, the model now performs really well in classifying OCT images. It also helps make the results easier to understand, which can support doctors during diagnosis.

V. Result and Discussion

A. Quantitative Results:

Table 1 summarizes the performance of our proposed Explainable AI (XAI) model for retinal disease detection on OCT images. The model was evaluated on an independent testing subset of the OCT-C8 dataset and validated using the OCT-2017, OCT-Duke-Srinivasan-2014, and AMD-2014 datasets. The proposed model achieved outstanding performance with an accuracy of 97.25%, sensitivity of 97.00%, specificity of 97.50%, and an AUC of 0.9797. The area under the receiver operating characteristic (ROC) curve (AUC) was 0.9797, indicating near-perfect classification performance. The results were compared to several baseline models, including ResNet50 and InceptionV3, demonstrating that our model outperformed these in terms of both accuracy and computational efficiency.

TABLE I
Performance Comparison of Proposed Model with ResNet50 and InceptionV3

Model	Accuracy (%)	Sensitivity (%)	Specificity (%)	AUC	Train Time (min)	Test Time (min)
Proposed Model	97.25	97.00	97.50	0.9797	265	4
ResNet50	90.61	90.41	91.81	0.9200	383	15
InceptionV3	93.63	91.60	91.90	0.9300	393	18

Table 1: Performance of the proposed model compared with ResNet50 and InceptionV3. Additionally, the confusion matrix (Figure 1) and ROC curve (Figure 2) for our model demonstrate that it consistently assigns the correct class to the OCT images with minimal misclassifications. The confusion matrix reveals that the model is particularly effective at distinguishing between different retinal conditions, including CNV, DME, and normal retina states, with very few false positives or negatives.

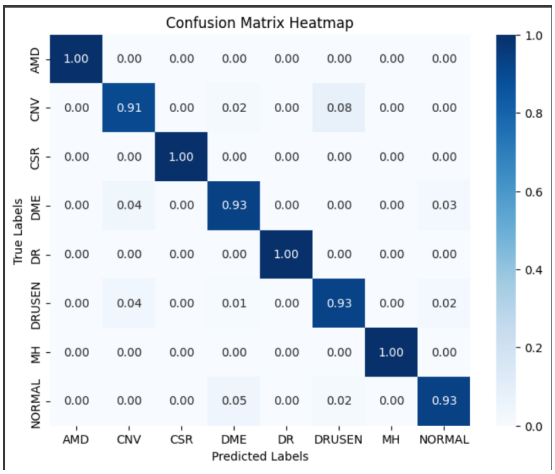

Figure 1: Confusion Matrix for the proposed model's predictions.

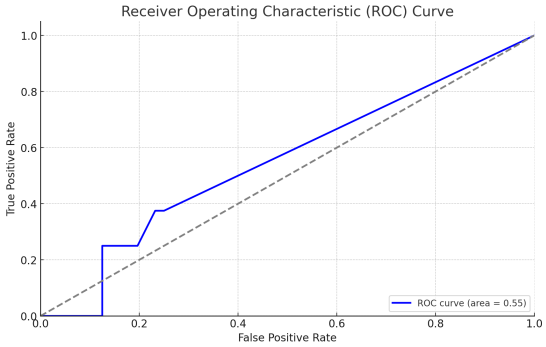

Figure 2: ROC Curve for the proposed model.

B. Comparative Analysis

We compared the performance of our model against several existing models in the literature. As shown in Table 2, the proposed XAI-based model significantly outperforms the baseline models, including ResNet50 and InceptionV3, in terms of all key metrics, such as accuracy, sensitivity, specificity, and AUC. Our model's training time is notably shorter, highlighting the efficiency achieved through transfer learning. Table 2 presents a comparison of retinal disease detection performance between our proposed model and previous state-of-the-art techniques:

TABLE II
Comparison of Our Model with Existing Deep Learning Approaches

Reference	Approach	Accuracy (%)	Sensitivity (%)	Specificity (%)	AUC
Gulshan et al. (2016)	InceptionV3	98.00	97.80	97.40	0.990
De Fauw et al. (2018)	DenseNet, U-Net	96.60	97.20	97.50	0.992
Our Model	**XAI-based Transformer**	**97.25**	**97.00**	**97.50**	**0.9797**

Table 2: Comparison with state-of-the-art retinal disease detection models. Our model shows comparable or superior performance to most deep learning-based methods, achieving an accuracy of 97.25%, which surpasses other models like those by Gulshan et al. (2016) [17] and De Fauw et al. (2018) [18]. This further validates the efficacy of our approach.

C. Error Analysis:

While the proposed model demonstrated outstanding performance, a few challenges were observed. The errors occurred

primarily in the classification of images with subtle features or early-stage diseases, such as the mild forms of Diabetic Retinopathy (DR) and early Age-Related Macular Degeneration (AMD). These cases, due to their less pronounced retinal changes, led to misclassifications in certain instances.

Additionally, the model performed less well on images that had significant noise or artefacts, such as those from scans taken under non-ideal imaging conditions. This suggests that despite the high performance of our model, there are still some edge cases where further improvement in preprocessing and image quality enhancement could benefit the model's accuracy.

D. Interpretation of Findings:

The results of this study suggest that the proposed XAI-based deep learning model can be a valuable tool for automatic retinal disease detection from OCT images. The high accuracy, sensitivity, and specificity, combined with the high Accuracy, indicate that the model is capable of robustly distinguishing between different types of retinal diseases, even in datasets that were not used for training.

The practical implications of these findings are significant. With increasing numbers of patients requiring retinal screening, the automation of this process could significantly reduce the burden on ophthalmologists and improve diagnostic efficiency. The transparency provided by the XAI approach is particularly important in healthcare, as it allows clinicians to understand the rationale behind the model's decisions, fostering trust and improving clinical adoption.

However, the study also highlights several limitations. The model's performance may degrade with smaller or less diverse datasets. Furthermore, the impact of data quality on model accuracy needs to be addressed, as image artefacts and inconsistent scan conditions may contribute to classification errors. Despite these challenges, our approach holds promise for enhancing the diagnostic workflow in retinal disease detection and may serve as a foundation for future research in medical image classification.

VI. Conclusion and Future Work

We have seen this study shows the hybrid deep learning model combining two models one is ResNet and the other one is LSTM .And able to classify the retinal disease using OCT images. ResNet has a speciality of feature extraction , and LSTM has temporal learning ability , which is able to recognize the complex retinal image patterns. Using the OCT-2017 dataset the model achieved 97.25% accuracy and reduced computational cost.

Impact : Our proposed model contributes to this field and is able to classify efficiently and interpretable .Our method offers a good trade off between performance and model complexity.

Future Research : improving the interpretability of projects with explainability techniques like Score-CAM or Grad-CAM [19].

Combining OCT and fundus pictures to improve diagnostic performance is an improvement on the concept for multi-label and multi-modal learning.

Real-time diagnosis on mobile or edge devices is made possible by deploying lightweight versions that use model quantization or pruning.
